WHAT IS BIOFILM?
Biopsies from chronic wounds show that 60% of the specimens contained biofilm structures [8].

**Figure**: Bacterial Biofilm Formation - 5 Stages:

<table>
<thead>

</tr>
<tr>
<td>Bacteria attach to a variety of surfaces, from metal, to plastic, to skin tissue, using specialized tail-like structures.</td>
<td>The cells grow and divide, forming a dense matrixed structure, many layers thick. At this stage the biofilm is too thin to be seen.</td>
<td>When there are enough bacteria in the developing biofilm the bacteria secrete a slimy extracellular matrix of proteins and polysaccarides.</td>
<td>The slime protects the bacteria from the harsh environments, shielding them from many chemicals, antibiotics and immune systems.</td>
<td>As the colonies mature, the structures created weaken and cast off bacteria that look for new places to grow and prosper.</td>
</tr>
</tbody>
</table>
Bacterial biofilm is a major barrier to wound healing

- Bacteria protected from topical agents
- Low oxygen in biofilm niches
- Impaired migration and proliferation of keratinocytes
- Bacteria protected from systemic antibiotics
- Host defenses unable to clear infection
Biofilms
Treatment of biofilms on teeth?
How do you treat biofilms on wounds?
EWMA Document:
Principle Role of Debridement

EWMA Document:
Debridement

An updated overview and clarification of the principle role of debridement

A EWMA Document
Debridement

- Frequency of Debridement's and Time to Heal: A retrospective Cohort study of 312,744 Wounds JAMA Dermatology July Page 1-8 (Wilcox, et.al.,2013)
  - The more frequent the debridements, the better the healing outcome
  - Diabetic foot wounds that were debrided over 12 weeks had a 5.3 times greater chance of healing (Armstrong, 2011)
Cleansing is not debridement

- Cleansing with water/saline defined as the removal of dirt (loose metabolic waste or foreign material)
Definition of Debridement

- removes adherent, dead or contaminated tissue from a wound
- Including wound edges and the peri-wound skin
Debridement removes:

- Exudate
- Slough
- Serocrusts
- Hyperkeratosis
- Necrosis
- Pus
- Haematomas
- Foreign bodies
- Debris
- Bone fragments
Benefits of Debridement

**Decrease**
- Odour
- Excess moisture
- Risk of infection
- Bacterial burden
- Pain
- **Biofilm**

**Stimulate**
- Wound edges
- Epithelialisation
- Wound healing

**Improve**
- normalises biochemistry e.g. normalising the matrix metalloproteinase (MMP) and TIMP balance
- Quality of life
Parameters influencing the decision for debridement and the choice of technique

- Pain
- Skill of the care giver
- Patients environment
- Resources of the care giver
- Patients choice and consent
- Regulations
- co-morbidities
- Local Guidelines
- Quality and stage of life
Patient consent for debridement

- Patient fear
- Any procedure should be thoroughly explained to the patient
- The patient should be forewarned about any manipulations (injection, tracking of tissue, application of the tourniquet)
- Pain is a very important issue in the treatment of wounds
- Appropriate anesthesia is essential in all types of debridement
- Some wounds are painless for example diabetic foot ulcers neuropathy, frostbite
Adequate Pain management

Topical
- EMLA 5 %
- Lignocaine 2 % Gel
- Morphine tincture 9 ml hydrogel/10mg Morphine

Systemic
- Fentanyl patches
- Entonox gas
- IV
- Nerve blocks
Indications for debridement

1. Define the problem (necrosis, eschar, slough, sources of infection)
2. Define the exudate levels of the wound bed ranging from dry to wet
3. Diagnosis of different kinds of tissue types and bioburden which cover the wound bed, the state of the wound edges and the peri-wound skin
Have a plan

• Define an aim
• Define a timeframe
• Define a method

Wound Characteristic
• Available skills
• Available resources
EWMA Document: Debridement

An updated overview and clarification of the principle role of debridement
Debridement – integrated management plan

Debridement is an integrated part of the management of a person with a wound, achieving certain goals and therefore creating a healthy wound bed, edges and peri-wound skin, with the objective of promoting and accelerating healing.
Debridement Quality cycle

Terminology

**Diagnosis:**
Diagnosis of bioburden, tissue type and factors influencing debridement.

**Decision:**
Decision on the outcome that should be achieved, the time by which it can be achieved and, depending on this, the techniques that should be used.

**Add On:**
Additional measures needed to secure a successful debridement process, such as optimising tissue for debridement, locally and additional systemic measures to secure successful debridement, e.g. relieve pressure, treat infection, induce blood flow and optimise comorbidities.

**Goal:**
If optimal debridement result has been achieved, continue the management of the individual with the wound. If optimal debridement has not been achieved, re-diagnose and repeat the debridement process cycle.

**Review:**
Review whether the outcome has been successfully achieved and whether the chosen debridement technique had proven to be valid in the specific treatment case.
Methods of Debridement

- Mechanical
- Autolytic
- Enzymatic
- Larval
- Ultrasound
- Sharp
- Surgical
Mechanical wound debridement involves the use of dry gauze dressings or wet to dry gauze dressings to remove non-viable tissue from the wound bed.
Limitations

- Gauze as a debridement agent is associated with significantly more pain for
- Frequent dressing changes to avoid pain
- The use of wet-to-dry, plain gauze and paraffin tulle as debriding agents has little to support their use
Monofilament pads

- Mono filament pads e.g. Debrisoft
- Can be quick and effective
- Less pain removes debris and exudate from wounds
Autolytic debridement

- Moist interactive wound dressings
- Hydrocolloids
- Hydrogels
- Occlusive dressing
- Semi-occlusive dressing
- Facilitates healing
Indications

Autolytic dressings are indicated for wounds with necrotic tissue or fibrin coatings to rehydrate, soften and liquefy hard eschar and slough.
Remember....

- Moist interactive dressings not always appropriate
- If there is no blood supply keep it dry
- Unless you are 100% sure there is viable tissue beneath or you have been advised by a WCNS or responsible physician
Wet slough

Terminology

Diagnosis:
Diagnosis of bioburden, tissue type and factors influencing debridement.

Decision:
Decision on the outcome that should be achieved; the time by which it can be achieved and, depending on this, the techniques that should be used.

Add on:
Additional measures needed to secure a successful debridement process, such as optimising tissue for debridement, locally and additional systemic measures to secure successful debridement, e.g., relieve pressure, treat infection, induce blood flow and optimise comorbidities.

Review:
Review whether the outcome has been successfully achieved and whether the chosen debridement technique had proven to be valid in the specific treatment case.

Goal:
If optimal debridement result has been achieved, continue the management of the individual with the wound. If optimal debridement has not been achieved, re-diagnose and repeat the debridement process cycle.
Compression!
Local infection
Wound Irrigation solution and gels containing antimicrobials

- Cleansing, rinsing and decontamination of acute and chronic skin wounds
- Helpful in the prevention of biofilm
Acetic Acid (Vinegar) soak

• 1 part of 5 % vinegar and 9 part saline/water = 0.5 %
• Soak gauze and leave on wound for 10 minutes
• Wash off mixture
• Continue with dressing plan
• Repeat daily for 5-7 days
• Especially beneficial against Pseudomonas aeruginosa

The solution to the pollution is in the dilution
